Background

- Ultrasonic Molecular Imaging
 - Uses targeted contrast agents
 - Attachment of specific ligands
 - Antibodies
 - Peptides
 - Polysaccharides
 - Bind to cellular receptors
 - Recognize disease antigens
 - Targeted Pathologies
 - Tumors
 - Inflammation
 - Thrombus

Targeted Ultrasound Contrast Agents

- Blood doesn't scatter US well
- Microbubble: A contrast agent
- Filled with gas: High echogenicity compared to liquid based particles or blood cells
- Diameters of the order of 1 to 5 μm
- Smaller than Red Blood Cells (6-8 μm)
- Improve the sensitivity of 2-D and 3-D ultrasound imaging

Structure of Microbubbles

- A monolayer amphiphilic phospholipid shell
- The water insoluble hydrocarbons
- Charged phosphate head groups
- Use of PEG:
 - Coalescence
 - Phagocytosis
 - Physical barrier to enzymatic agents, adsorption of blood proteins

Current Contrast Agent Production

- produced by mechanical agitation of lipid solution
- polydisperse size distribution

Large Size Variance:

Problems with Current Contrast Agents & Ultrasound Systems for Molecular Imaging

- Size distribution
- The resonant frequency

- Limited frequency bandwidth
- Only a small percentage of the contrast agents have diameters which result in resonant frequencies optimized for the limited bandwidth
- Fewer contrast agents retained
- Filtering does not work on lipid-shelled bubbles

The Problem

bubble size= 1.8 ± 1.5 microns

$F_{\text{bandwidth}}^{\text{receiver}} = 5.0 \pm 1.5$ MHz

detectable bubbles: 18%

A Solution

bubble size= 1.8 ± 0.2 microns

$F_{\text{bandwidth}}^{\text{receiver}} = 5.0 \pm 1.5$ MHz

detectable bubbles: 92%

Monodisperse Microbubble Production

- Use of Microfluidic Flow Focusing Device

Talu, et al., *Langmuir*, 2006
Hettiarachchi et al., *Lab Chip*, 2007

Why use a Microfluidic System?

- Relatively cheap, simple, and easy to multiplex

(video playback at 1/100 speed)

50 μm

Tailoring the Size Distribution Microbubbles

Lipid Encapsulation for Stability

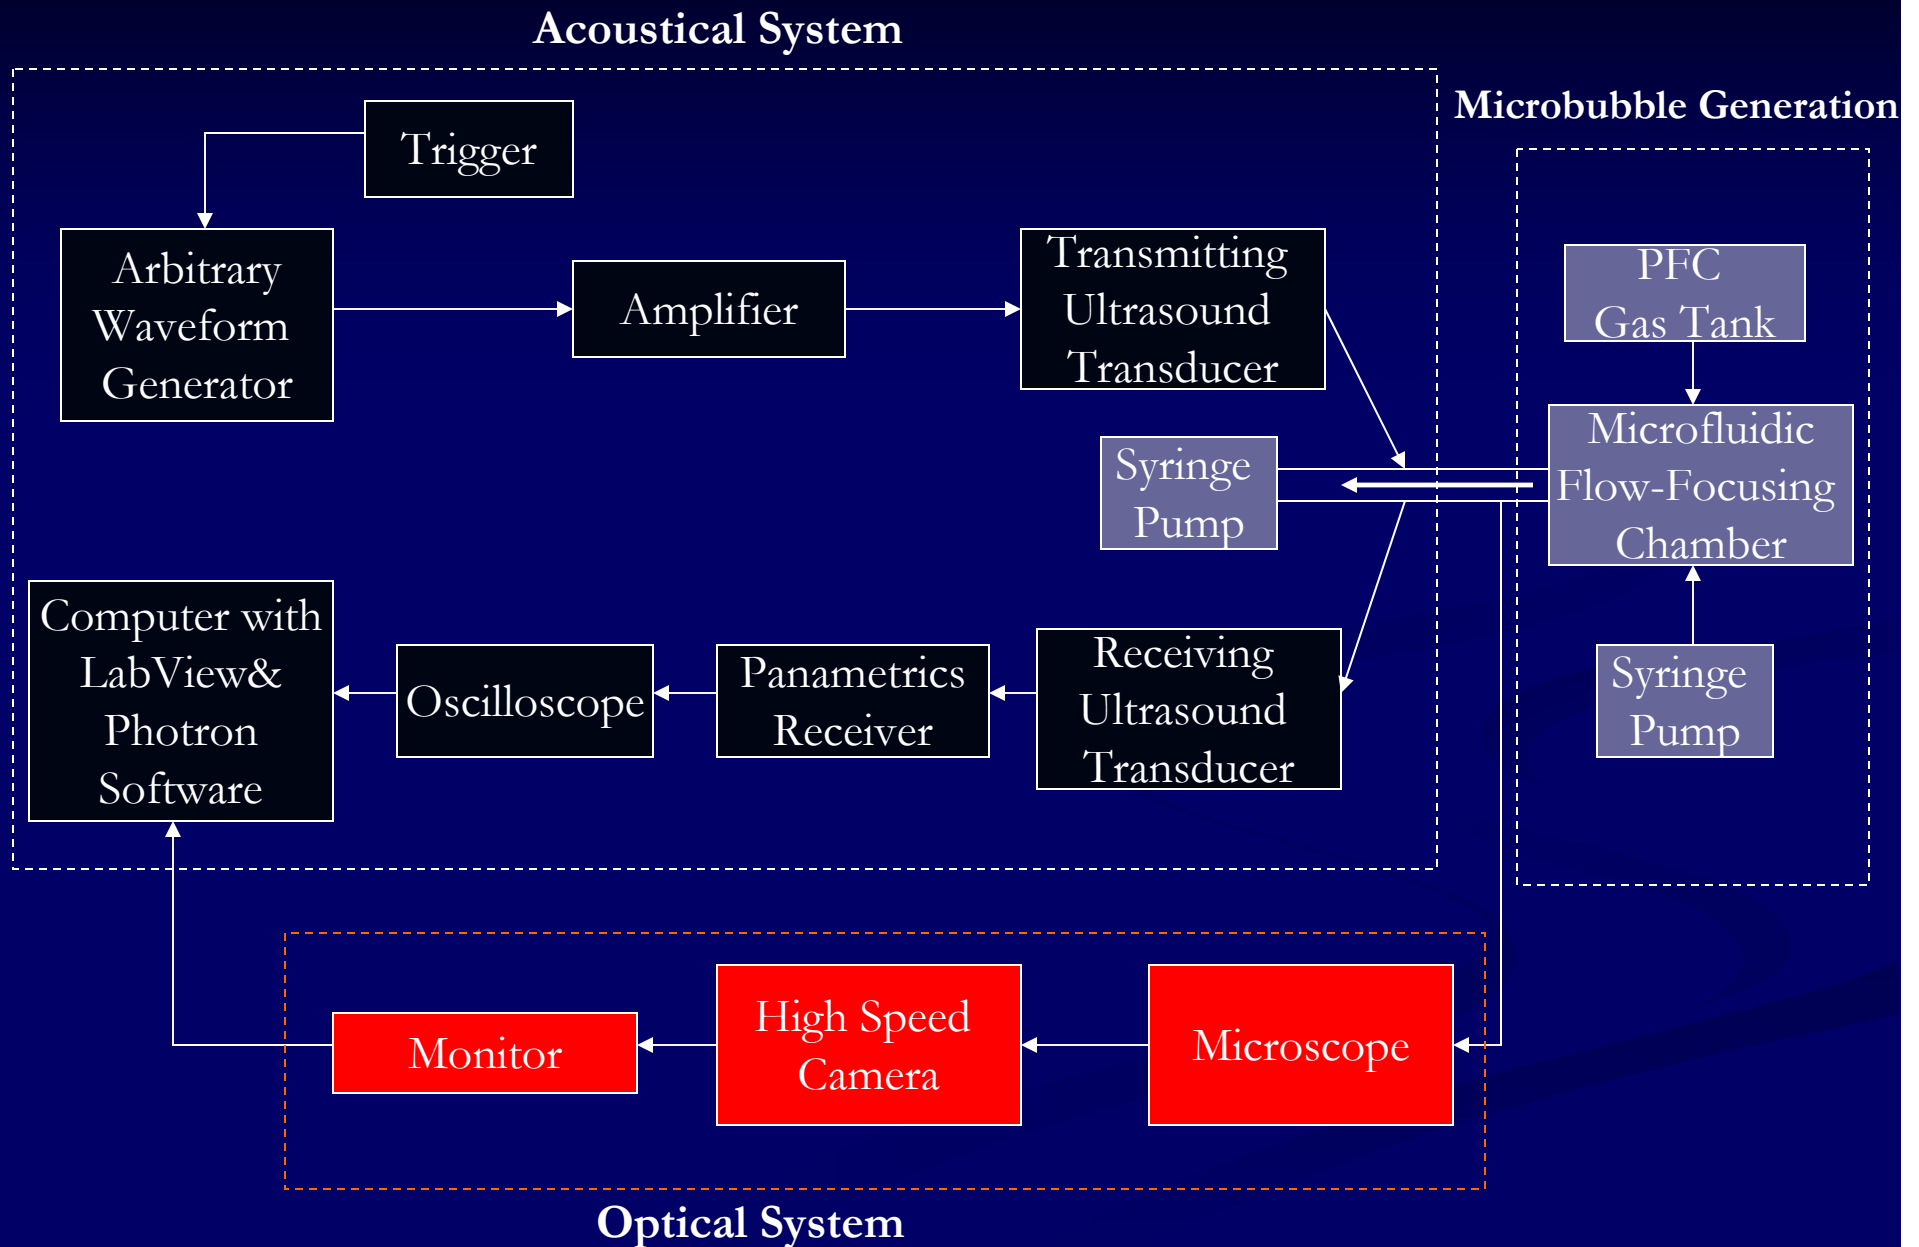

Cell Targeting

Incorporate Targeting Ligand

Ultrasound Imaging System

Microfluidic Flow Focusing Device

Microtube

US Transducers

- Ultrasound Transducers
- Transmitter 2.5 MHz
/Receiver 5 MHz
- Liquid flow rate: 35 $\mu\text{l}/\text{min}$
- PFC flow rate: $\sim 2\text{-}4$ psi

Acoustic Studies of Monodisperse Contrast Agents

- Standard deviation of echo amplitude is smaller
- Correlation coefficient 0.95 vs. 0.70
- Improved Signal Response of Monodisperse Contrast Agents

Detection of Monodisperse Agents

Monodisperse

Polydisperse

Summary & Conclusions

- Successful production of monodisperse contrast agents
- Monodisperse microbubble contrast agents have the potential to increase sensitivity in ultrasound molecular imaging
- More sensitive detection of monodisperse contrast agents compared to polydisperse agents
- Production rate of contrast agents is one of the challenges (in comparison to $\sim 10^{10}$ μl with polydisperse)
